

A 100x100 grid with a complex pattern of black, white, and gray squares. A green zigzag line starts at the bottom left and moves towards the top right, passing through a 10x10 black square region in the bottom right corner.

Color in the QR code modules. If a module contains only a diagonal line, color only the upper left half. Only color in modules that lie on the green line.

For each (interleaved) data digit (4 consecutive bits along the green line), fill it inside the block table. Interpret squares with a diagonal line as inverted.

0 : 0000	8 : 1000
1 : 0001	9 : 1001
2 : 0010	A : 1010
3 : 0011	B : 1011
4 : 0100	C : 1100
5 : 0101	D : 1101
6 : 0110	E : 1110
7 : 0111	F : 1111

[illegible][illegible]

Now, decode the data. Read the data block-by-block, essentially concatenating the blocks. The first digit indicates the encoding mode: 1 for numeric, 2 for alphanumeric, 4 for byte. If it's not byte, this tutorial will not work - sorry! The next two digits represent the number of characters to read. After, each two digits together form a number from 0 to 255, representing the ASCII values. It's easy to memorize: 31 (hex) is '1', 41 is 'A', 61 is 'a', 2E is '.', 2F is '/', and 3A is ':' (full table on page 7).
